

ABSTRACT OF THE DISCLOSURE

A check chip of a sensor measuring device is provided with a structural characterizing portion of a convex shape, concave shape or a penetration hole at a location where a user is considered to pick the check chip up. The state of the structural characterizing portion is made to be different from that of a structural characterizing portion provided on a correction chip which is similar to the check chip, in size, the number of the structural characterizing portions, or placement location. Therefore, the difference from the correction chip can be easily identified even by a visually handicapped person or a weak-sighted person, according to the difference in the structural characterizing portion, from feel, thereby preventing the person from using the check chip and the correction chip with confusion.
